# Data analysis tasks in detectors

## ① Track finding

Reconstruction of particle trajectories from hits in detectors

## ② Budgeted classification

Real-time classification of events in triggers

## ③ Classification of signal / background events

Offline statistical analysis for discovery of new particles

# The Kaggle Higgs Boson challenge (in HEP terms)

- Data comes as a finite set

$$\mathcal{D} = \{(\mathbf{x}_i, y_i, w_i) | i = 0, \dots, N-1\},$$

where  $\mathbf{x}_i \in \mathbb{R}^d$ ,  $y_i \in \{\text{signal}, \text{background}\}$  and  $w_i \in \mathbb{R}^+$ .

- The goal is to find a region  $\mathcal{G} = \{\mathbf{x} | g(\mathbf{x}) = \text{signal}\} \subset \mathbb{R}^d$ , defined from a binary function  $g$ , for which the background-only hypothesis can be rejected at a strong significance level ( $p = 2.87 \times 10^{-7}$ , i.e., 5 *sigma*).
- Empirically, this is approximately equivalent to finding  $g$  from  $\mathcal{D}$  so as to maximize  $\text{AMS} \approx \frac{s}{\sqrt{b}}$ , where
  - $s = \sum_{\{i | y_i = \text{signal}, g(\mathbf{x}_i) = \text{signal}\}} w_i$
  - $b = \sum_{\{i | y_i = \text{background}, g(\mathbf{x}_i) = \text{signal}\}} w_i$

# The Kaggle Higgs Boson challenge (in ML terms)

Find a binary classifier

$$g : \mathbb{R}^d \mapsto \{\text{signal}, \text{background}\}$$

maximizing the objective function

$$AMS \approx \frac{s}{\sqrt{b}},$$

where

- $s$  is the **weighted** number of true positives
- $b$  is the **weighted** number of false positives.

- Ensembles of neural networks (1st and 3rd) ;
- Ensembles of regularized greedy forests (2nd) ;
- Boosting with regularization (XGBoost package).
- Most contestants did not optimize AMS directly ;
- But chose the prediction cut-off maximizing AMS in CV.

# Lessons learned (for machine learning)

- AMS is **highly unstable**, hence the need for
  - Rigorous and stable cross-validation to avoid overfitting.
  - Ensembles to reduce variance ;
  - Regularized base models.

- Support of samples weights  $w_i$  in classification models was key for this challenge.
- Feature engineering hardly helped. (Because features already incorporated physics knowledge.)

# Lessons learned (for physicists)

- Domain knowledge hardly helped.
- Standard machine learning techniques, run on a single laptop, beat benchmarks without much efforts.
- Physicists started to realize that **collaborations with machine learning experts is likely to be beneficial.**
  - *I worked on the ATLAS experiment for over a decade [...] It is rather depressing to see how badly I scored. – Andrew John Lowe*
  - *The final results seem to reinforce the idea that the machine learning experience is vastly more important in a similar contest than the knowledge of particle physics. I think that many people underestimate the computers. – Lubos Motl*
  - *It is probably the reason why ML experts and physicists should work together for finding the Higgs. – phunter*

# Scientific software in HEP

- ROOT and TMVA are standard data analysis tools in HEP.
- Surprisingly, this HEP software ecosystem proved to be rather limited and easily outperformed (at least in the context of the Kaggle challenge).

# Scikit-Learn in Particle Physics?

- The main technical blocker for the larger adoption of Scikit-Learn in HEP remains the **full support of sample weights** throughout all essential modules.
  - Since 0.16, weights are supported in all ensembles and in most metrics.
  - Next step is to add support in grid search.

Arnaud Joly  
@JolyArnaud

Gradient boosting with sample weight is in  
[@scikit\\_learn github.com/scikit-learn/s...](https://github.com/scikit-learn/scikit-learn/pull/10244)  
Thanks to @pprett.  
Used by many in the [#higgsml](#) challenge!

- In parallel, domain-specific packages are getting traction
  - ROOTpy, for bridging the gap between ROOT data format and NumPy;
  - `lhcb_trigger_ml`, implementing ML algorithms for HEP (mostly Boosting variants), on top of scikit-learn.

# Major blocker : social reasons ?

The adoption of external solutions (e.g., the scientific Python stack or Scikit-Learn) appears to be slow and difficult in the HEP community because of

- No ground-breaking added-value ;
- The learning curve of new tools ;
- Lack of understanding of non-HEP methods ;
- Isolation from the community ;
- Genuine ignorance.

Tim Head  
@betatim

Some times particle physicists make me laugh...someone just "discovered" [@scikit\\_learn](#) &ppl are amazed how awesome it is,watch out [@glouppe](#)

# Conclusions

- Scikit-Learn has the potential to become an important tool in HEP. But we are not there yet [WIP].
- Overall, both for data analysis and software aspects, this calls for a **larger collaboration between data sciences and HEP**.

*The process of attempting as a physicist to compete against ML experts has given us a new respect for a field that (through ignorance) none of us held in as high esteem as we do now.*
